Find the shortest path in a maze

Given a maze in the form of a binary rectangular matrix, find the shortest path's length in the maze from a given source to a given destination. The path can only be constructed out of cells having value 1, and at any moment, we can only move one step in one of the four directions.

The valid moves are:

Go Top: $(x, y) \longrightarrow (x - 1, y)$

Go Left: $(x, y) \longrightarrow (x, y - 1)$

Go Down: $(x, y) \longrightarrow (x + 1, y)$

Go Right: $(x, y) \longrightarrow (x, y + 1)$

For example, consider the following binary matrix. If source = $(0, 0)$ and destination = $(7, 5)$, the shortest path from source to destination has length 12.

```
[ 1 1 1 1 1 0 0 1 1 1 ]  
[ 0 1 1 1 1 1 0 1 0 1 ]  
[ 0 0 1 0 1 1 1 0 0 1 ]  
[ 1 0 1 1 1 0 1 1 0 1 ]  
[ 0 0 0 1 0 0 0 1 0 1 ]
```

```
[0 1 1 1 1 1 1 1 0 0]
[1 1 1 1 1 0 0 1 1 1]
[0 0 1 0 0 1 1 0 0 1]
```

Practice this problem

To find the maze's shortest path, search for all possible paths in the maze from the starting position to the goal position until all possibilities are exhausted. We can easily achieve this with the help of [backtracking](#). The idea is to start from the given source cell in the matrix and explore all four paths possible and recursively check if they will lead to the destination or not. Then update the minimum path length whenever the destination cell is reached. If a path doesn't reach the destination or explored all possible routes from the current cell, backtrack. To make sure that the path is simple and doesn't contain any cycles, keep track of cells involved in the current path in a matrix, and before exploring any cell, ignore the cell if it is already covered in the current path.

Following is the C++, Java, and Python implementation of the idea:

C++

Java

Python

```
1  import sys
2
3
4  # Check if it is possible to go to (x, y) from the current position.
5  # function returns false if the cell is invalid, has value 0 or already
6  def isSafe(mat, visited, x, y):
7      return 0 <= x < len(mat) and 0 <= y < len(mat[0]) and \
8             not (mat[x][y] == 0 or visited[x][y])
9
10
11 # Find the shortest possible route in a matrix `mat` from source cell
12 # to destination cell `dest`.
13
14 # `min_dist` stores the length of the longest path from source to a d
15 # found so far, and `dist` maintains the length of the path from a so
```

```

19
20     # if the destination is found, update `min_dist`
21     if (i, j) == dest:
22         return min(dist, min_dist)
23
24     # set (i, j) cell as visited
25     visited[i][j] = 1
26
27     # go to the bottom cell
28     if isSafe(mat, visited, i + 1, j):
29         min_dist = findShortestPath(mat, visited, i + 1, j, dest, min
30
31     # go to the right cell
32     if isSafe(mat, visited, i, j + 1):
33         min_dist = findShortestPath(mat, visited, i, j + 1, dest, min
34
35     # go to the top cell
36     if isSafe(mat, visited, i - 1, j):
37         min_dist = findShortestPath(mat, visited, i - 1, j, dest, min
38
39     # go to the left cell
40     if isSafe(mat, visited, i, j - 1):
41         min_dist = findShortestPath(mat, visited, i, j - 1, dest, min
42
43     # backtrack: remove (i, j) from the visited matrix
44     visited[i][j] = 0
45
46     return min_dist
47
48
49 # Wrapper over findShortestPath() function
50 def findShortestPathLength(mat, src, dest):
51
52     # get source cell (i, j)
53     i, j = src
54
55     # get destination cell (x, y)
56     x, y = dest
57
58     # base case
59     if not mat or len(mat) == 0 or mat[i][j] == 0 or mat[x][y] == 0:
60         return -1
61
62     # `M x N` matrix
63     (M, N) = (len(mat), len(mat[0]))
64
65     # construct an `M x N` matrix to keep track of visited cells
66     visited = [[False for _ in range(N)] for _ in range(M)]
67
68     min_dist = findShortestPath(mat, visited, i, j, dest)
69
70     if min_dist != sys.maxsize:
71         return min_dist
72     else:
73         return -1

```

```
76 if __name__ == '__main__':
77
78     mat = [
79         [1, 1, 1, 1, 1, 0, 0, 1, 1, 1],
80         [0, 1, 1, 1, 1, 1, 0, 1, 0, 1],
81         [0, 0, 1, 0, 1, 1, 1, 0, 0, 1],
82         [1, 0, 1, 1, 1, 0, 1, 1, 0, 1],
83         [0, 0, 0, 1, 0, 0, 0, 1, 0, 1],
84         [1, 0, 1, 1, 1, 0, 0, 1, 1, 0],
85         [0, 0, 0, 0, 1, 0, 0, 1, 0, 1],
86         [0, 1, 1, 1, 1, 1, 1, 1, 0, 0],
87         [1, 1, 1, 1, 1, 0, 0, 1, 1, 1],
88         [0, 0, 1, 0, 0, 1, 1, 0, 0, 1]
89     ]
90
91     src = (0, 0)
92     dest = (7, 5)
93
94     min_dist = findShortestPathLength(mat, src, dest)
95
96     if min_dist != -1:
97         print("The shortest path from source to destination has length", min_dist)
98     else:
99         print("Destination cannot be reached from source")
100
```

[Download](#) [Run Code](#)

Output:

The shortest path from source to destination has length 12

The time complexity of the above backtracking solution will be higher since all paths need to be traveled. However, since it is the shortest path problem, [Breadth-first search \(BFS\)](#) would be an ideal choice. If BFS is used to solve this problem, we travel level by level. So the destination node's first occurrence gives us the result, and we can stop our search there. The BFS approach is discussed [here](#).
